## Module Goals

### Answer questions about a collection...

- Do **All()** items meet a condition
- Do **Any()** items meet a condition
- Collection **Contains()** an item?

### Use an **EqualityComparer<T>** for classes

# All() Method

# Uses of All() Method

**Are all products' price greater than their cost?**

**Do all sales orders have a quantity greater than or equal to 1?**

**Do all customers have a zero balance?**

```
IEnumerable<T>.All(predicate);
```

```
products.All(prod =>  
    prod.ListPrice > prod.StandardCost);
```

- ◀ **All() searches the entire collection**
- ◀ **Determines if all items match the condition**
- ◀ **Do all products' list price exceed their cost?**

## Demo

**All()** method

# **Any() Method**

# Uses of Any() Method

**Do any sales orders  
have a quantity  
greater than 10**

**Do any sales orders  
have a total greater  
than 10k?**

**Do any customers  
have a credit  
balance?**

```
IEnumerable<T>.Any(predicate);
```

```
sales.Any(sale =>  
    sale.LineTotal > 10000);
```

- ◀ **Any() method searches entire collection**
- ◀ **Determines if *any* items in collection match the condition**
- ◀ **Do any sales have a line total greater than 10,000?**

## Demo

**Any() method**

# **Contains() Method**

# Contains() Method

**Searches collection  
to see if a value  
exists**

**For simple data type  
collections such as  
int, decimal, string,  
etc.**

**Checks if value in  
the collection is  
equal to value you  
are searching for**

## Demo

**Contains using an integer list**

# Contains() with Objects

**Default is to  
compare object  
references**

**You probably want  
to look at the value  
in one or more  
properties of an  
object**

**Need to create  
EqualityComparer<T  
> class**

```
public class ProductIdComparer :  
    EqualityComparer<Product>  
{  
    public override bool Equals(Product x,  
                                Product y)  
    {  
        return (x.ProductID == y.ProductID);  
    }  
  
    public override int  
        GetHashCode(Product obj) {  
        return obj.ProductID.GetHashCode();  
    }  
}
```

◀ **Inherit from EqualityComparer<Product>**

◀ **Override Equals(product 1, product 2) method**

◀ **Return true if both match**

◀ **Override GetHashCode() method**

◀ **Create a unique value from one or more properties**

## Demo

**Contains() using a comparer class**

## Module Summary

**All()** checks if all items match a predicate

**Any()** checks if any items match a predicate

**Contains()** with a comparer make it easy to search object property values

**Need to build a comparer class for each type of search you wish to perform**
